1. INTRODUCTION:

- The Development Phase is an important stage of the project in which the planned requirements are converted into a working system.
- In this phase, the required table, fields, choice values, reference fields, and automation components are created in the Service Now platform.
- The main purpose of this phase is to develop the backend structure required for the Auto Ticket Classification using Flow Designer project.

2. CREATION OF CUSTOM TABLE:

A custom table named Incident Workflow is created to store the IT support ticket records.

Steps to Create Custom Table

- Open All menus.
- Search for Tables.
- Under System Definition, select Tables.

- Click the New button.
- Enter the Label as Incident Workflow.
- Uncheck the Create Module option.
- Save the Form.
- Enable the Auto Number option under the Controls section.
- Save the Form again.

The custom table is used to store and manage the ticket information.

3. FIELD CREATION AND CONFIGURATION:

After creating the table, the required fields are created with appropriate data types.

The main fields include:

FIELD LABEL	DATA TYPE
Number	Auto Number
Caller	Reference
Category	Choice
Subcategory	Choice
Short Description	String
Description	String
State	Choice
Assigned Group	Reference
Assigned to	Reference

These fields provide structured information for each IT support ticket.

4. CHOICE FIELD CONFIGURATION:

Choice values are added to the required fields.

Category:

- Network
- Hardware

- Access
- Performance

Subcategory:

- Wi-Fi
- Projector
- Forgot Password
- Slow Computer

State:

- New
- In progress
- On hold
- Resolved
- Closed

These choice values provide standardized ticket information.

5. DEPENDENCY CONFIGURATION:

- ❖ A dependency is created between the Category and Subcategory fields.
- ❖ The Subcategory field is configured as dependent on the Category field.

The dependency is defined as:

- **Network** → Wi-Fi
- **Hardware** → Projector
- **Access** → Forgot Password
- **Performance** → Slow Computer

This ensures that the Subcategory options are displayed according to the selected Category.

6. FLOW DESIGNER CONFIGURATION:

After completing the backend configuration, the automatic ticket classification is developed using Flow Designer.

- A new Flow is created with the name:
- Auto Classify School IT Tickets
- The application is set as Global.

The Flow is designed to automatically process a ticket when a new record is created.

Trigger Configuration:

Trigger: Record Created

Table: Incident Workflow

Condition: Category is Empty

This trigger starts the classification process when a new ticket is created.

7. AUTOMATIC CLASSIFICATION:

The Flow Designer uses conditions to identify the issue from the Short Description.

The classification logic is:

1. **Wi-Fi** → Category = Network → Subcategory = Wi-Fi
2. **Projector** → Category = Hardware → Subcategory = Projector
3. **Password / Login** → Category = Access → Subcategory = Forgot Password
4. **Slow / Hanging** → Category = Performance → Subcategory = Slow Computer

After identifying the issue, the Flow updates the ticket record with the appropriate Category and Subcategory.

8. EMAIL NOTIFICATION CONFIGURATION:

An email notification is configured after the ticket classification process.

The Flow Designer uses the Send Email action.

The email is sent to:

Caller → Email

Subject:

Your Request for the issue has been submitted.

The email body contains the ticket confirmation message.

This allows the caller to receive confirmation after the ticket is created.

9. ACTIVATION OF FLOW:

After completing all the required conditions and actions, the Flow is checked and activated.

The Activate option is selected from the top-right corner of the Flow Designer.

Once activated, the Flow is ready to process newly created Incident Workflow records.

10. DEVELOPMENT RESULT:

The development phase successfully creates the basic working components of the system.

The following components are developed:

- Incident Workflow custom table.
- Required fields and data types.

- Category and Subcategory choices.
- Category and Subcategory dependency.
- Automatic ticket classification Flow.
- Email notification action.

These components provide the required foundation for testing the complete system.

11. CONCLUSION:

- The Development Phase converts the planned requirements into a working ServiceNow configuration.
- The Incident Workflow table and required fields are created, followed by Category and Subcategory configuration and dependency setup.
- The Flow Designer automation is then developed to automatically classify IT support tickets based on the Short Description and assign the appropriate Category and Subcategory.

Finally, email notification is configured to inform the caller after ticket creation.

- Thus, the Development Phase provides the required backend configuration and automation for the next stage of the project, which is Testing and Validation.
