1. Introduction:

Requirement Analysis and Planning is the first and most important phase of the Auto Ticket Classification using Flow Designer project. The main purpose of this phase is to understand the existing problem, identify the requirements of the system, define the objectives, and plan the development activities. The school IT helpdesk receives multiple incident requests every day from students and teachers. These requests may be related to Wi-Fi problems, projector failures, password issues, slow computers, and other common IT problems. Currently, IT staff manually review each support request and identify the appropriate Category and Subcategory. This manual process requires additional time and may result in incorrect classification. The proposed system is designed to automate this classification process using Service Now Flow Designer. The system analyzes the Short Description and Description fields and automatically assigns the appropriate Category and Subcategory. A The reference project identifies manual ticket review and classification as the main problem and proposes Flow Designer-based automation as the solution.

2. Problem Statement:

The school IT helpdesk receives a large number of support requests from students and teachers.

2.1 Common requests include:

- Wi-Fi connectivity problems.
- Projector failures.

- Forgotten password problems.
- Slow computer issues.
- Network-related issues.
- Hardware-related issues.
- Account access problems.

Currently, IT staff manually examine each ticket and determine its issue type.

2.2 The manual process includes:

1. Reviewing the ticket.
2. Understanding the issue.
3. Identifying the issue type.
4. Selecting the appropriate Category.
5. Selecting the appropriate Subcategory.
6. Informing the caller about ticket creation.

This process is time-consuming and may become difficult to manage when the number of support requests increases. Therefore, an automated ticket classification system is required to reduce manual effort and improve ticket processing efficiency.

3. Existing System:

- In the existing system, IT support tickets are manually reviewed by IT staff.
- When a student or teacher submits a support request, the IT staff member checks the issue description and manually selects the appropriate Category and Subcategory.
- Limitations of Existing System

The major limitations are:

- Manual ticket classification.
- More time required for processing.
- Possibility of classification errors.
- Repeated manual work for IT staff.

The reference identifies the existing manual process as time-consuming, error-prone, and difficult to scale as request volume increases.

4. Proposed System:

The proposed system introduces automatic ticket classification using ServiceNow Flow Designer. In the proposed system, the user provides the required ticket information and enters a Short Description describing the issue. The Flow Designer automatically analyzes the issue description and identifies predefined keywords.

For example:

Wi-Fi issue

→ **Category** = Network

→ **Subcategory** = Wi-Fi

Projector issue

→ **Category** = Hardware

→ **Subcategory** = Projector

Password issue

→ **Category** = Access

→ **Subcategory** = Forgot Password

Slow computer issue

→ **Category** = Performance

→ **Subcategory** = Slow Computer

After classification, an automated email notification is sent to the caller.-

5. Objectives of the Project:

The major objectives of the project are:

- To automatically classify IT incidents when they are created.
- To reduce manual effort for IT support staff.
- To improve ticket routing efficiency.
- To provide consistent Category and Subcategory values.

The reference document specifically identifies automatic classification, reduced manual effort, improved routing efficiency, and a no-code maintainable solution as the major objectives.=-
